How much power does a data center rack have?

While power density per rack averaged 6 kW in 2006, it climbed to about 8 kW by 2012, and is expected to approach 12 kW per rack by 2014, according to data collected by the Data Center Users Group, sponsored by Vertiv™. The need now exists for taller, wider and deeper racks to accommodate the changes in IT equipment and densities.

Is 12 kW enough for a data center?

According to AFCOM's 2024 State of the Data Center Report, average rack density now sits around 12 kW. That's 2x the 6.1 kW per rack they initially reported in 2016. Despite doubling average density in just eight years, 12 kW still isn't enough. Data center operators are being asked to support 30 kW+ per rack.

What percentage of data centers have less than 10kW racks?

It's important to note that 37 percent of data centers still have racks of less than 10kW. There are three key reasons why these data centers have not seen substantial increases in rack density. Server virtualization has been around for decades, and containerization has been used for several years.

What is a data center rack density?

As a result, data center rack densities are increasing. Rack density refers to the amount of power consumed by all of the IT equipment in the rack. For many years, rack densities averaged 2kW to 5kW. That's not the case anymore. According to AFCOM's 2024 State of the Data Center Report, average rack density now sits around 12 kW.
