How high should a network cabinet be?

With installations in existing buildings, there may be building shortcomings (no raised floor, low ceiling, concrete pillars in the room, etc.) that can influence the traditional 78-inch height of the network cabinet. Therefore, it is important to have a variety of choices in heights and depths when evaluating the cabinet design.

What equipment is included in a network cabinet?

Sometimes, a network cabinet not only includes server equipment but also computer equipment, such as keyboards and monitors. Design issues that arise are space and accessibility. Many network enclosures offer various options when mounting these devices into the enclosure.

Which cooling device design is best for network cabinets?

Several cooling device designs for network cabinets that have been proven to dissipate heat include perforated front and rear doors and vented roofs. Air flow for servers is normally designed to blow front-to-back, but other designs exist—right to left or bottom to top. A crucial climate design issue is venting hot air and bringing in cool air.

How much power does a 1U server use?

While this equipment is smaller, it still requires the same amount of power. In one example, a new 1U server is rated at approximately 190W, so 42 of these servers in a single cabinet would produce over 8,000W of heat. The idea that technology is getting smaller, faster, and better is certainly one that can't be argued.
